MSc - Data Mining

Topic 01: Module Overview

Part 06 : Top X pandas commands

Dr Bernard Butler and Dr Kieran Murphy

Department of Computing and Mathematics, WIT. (bbutler@tssg.org; kmurphy@wit.ie)

Spring Semester, 2021

Outline

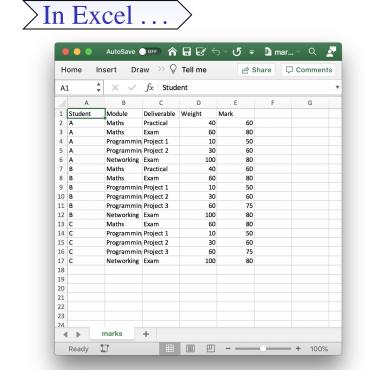

- Reading data formats
- Computing descriptive statistics
- Processing data by filtering and grouping

Part I

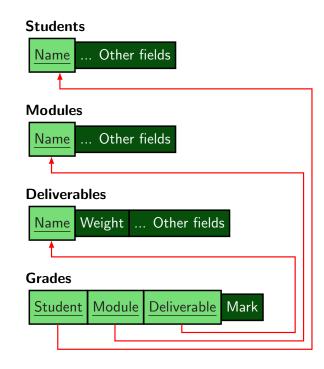

Introduction

Minimal Dataset

To better understand the various pandas operations we are going use a tiny* dataset based on (fictional) student results. (marks.csv)

$\rangle \dots$ like to know $\dots \rangle$

- Student performance —
 weighted mark on each
 module, missing deliverables
 etc.
- Module performance number of attempts and average mark.
- Deliverable performance number of attempts and average mark, predictor of overall module grade, etc.

^{*}Dataset is small enough that you can verify operation results by hand.

Terminology

0 1 2	A A	Module Maths	Deliverable	Weight	Monk
1		Maths		_	Mark
-	Α		Practical	40	60
2		Maths	Exam	60	80
	Α	Programming	Project 1	10	50
3	Α	Programming	Project 2	30	60
4	Α	Networking	Lab Work	100	80
5	В	Maths	Practical	40	60
6	В	Maths	Exam	60	80
7	В	Programming	Project 1	10	50
8	В	Programming	Project 2	30	60
9	В	Programming	Project 3	60	75
10	В	Networking	Project	100	80
11	С	Maths	Exam	60	80
12	С	Programming	Project 1	10	50
13	С	Programming	Project 2	30	60
14	С	Programming	Project 3	60	75
15	С	Networking	Lab Work	100	80

- A DataFrame is a table of data values.
 - df = pd.read_csv("marks.csv")
- A Series is a list of data values typically columns in a dataframe. We can access an individual column using
 - df.Deliverable
 df["Deliverable"]
 df.iloc[:,2]
 (dict notation)
 (numpy, index notation)
- The index is a special column whose values can be used to access rows rather using row number.
 - The default index is equal to the row number.

Part II

Input and Output

Setup

Minimal

We begin every data mining project with importing the three core data science packages:

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
plt.style.use('seaborn-darkgrid')

import numpy as np
numpy — fast array operations
pandas — data manipulation
matplotlib — visualisation
```

• We give modules nicknames (np, pd, ...) to simplify their later use, and we access properties/functions of a package using the dot notation (np.max, pd.DataFrame, ...).

Extra >

```
import seaborn as sns
import statsmodels.api as sm

pd.set_option('display.max_columns', 500)
pd.set_option('display.width', 1000)
seaborn — statistical visualisation
statsmodels — statistical data exploration
pandas options to show all columns for wider datasets
```

Reading data from a CSV file

Pandas supports a huge variety of input/output formats so best approach is to focus on what is needed to process the given data and verify input. Our marks dataset is in CSV format so we start with

```
import numpy as np
  import pandas as pd
  import matplotlib.pyplot as plt
  plt.style.use('seaborn-darkgrid')
                                                                                      (16, 5)
and input using
                                                                                        Student
                                                                                                Module Deliverable Weight
                                                                                                 Maths
                                                                                                      Practical
                                                                                                                  60
                                                                                                 Maths
                                                                                                              60
                                                                                                                  80
                                                                                                        Exam
  df = pd.read_csv('marks.csv', sep=',')
                                                                                           A Programming
                                                                                                       Project 1
  print(df.shape)
                                                                                                              100
                                                                                              Networking
                                                                                                      Lab Work
  df.head()
                                                  (16, 5)
```

Always verify input by checking dataset dimensions and looking at some rows!!!

Datatypes

Pandas data types:

- **object** used for text or mixed numeric and non-numeric values.
- int64 integer values,

• Does not support missing values, so an int column containing at least one missing value will automatically be converted to float.

Student

Module

Weight

dtype: object

Mark

Deliverable object

object

object

int64

int64

- float64 floating point numbers.
- bool True/False values
- datetime64 date and time values
- category Finite (typically small) list of text values

df.dtypes

Regularly verifying datatypes is vital[†]:

- Operations differ based on datatype, eg, '+' concatenate strings but adds numerical values.
- Datatype can change based on results, eg, int converts to float due to missing values.

[†]Google "Detecting Excel's gene auto-conversions."

Datatypes — Converting

We will deal with modifying and creating new columns later, but while we are on datatypes, we will look at changing datatype . . .

Using the Series function astype

```
df["Weight"] = df["Weight"].astype('float')
df["Weight"].dtype
dtype('float64')
```

- New datatype is required argument 'int', 'float', 'str', 'object', 'category', etc.
- Simple, but fragile if data conversion is possible.

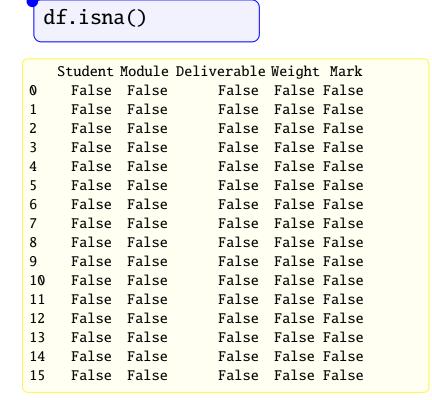

```
or using pandas function to_numeric
```

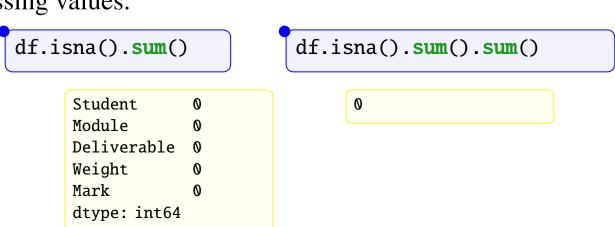

```
df["Weight"] = pd.to_numeric(df["Weight"])
df["Weight"].dtype
dtype('float64')
```

- More powerful, can specify what to do in cases where the conversion fails etc
- Have functions to_numeric, to_datetime, and to_timedelta.

Missing Values

Identifying and dealing with missing values is critical step in data preparation. What should you do? delete rows containing missing values? or impute then? Here we will just look at identifying missing values.

- Use dataframe function fillna to replace missing values.
- Recall False and True map to 0 and 1 respectively.
- Use df.isna().sum(axis=1) to sum along rows.

Output

Saving dataframe to CSV is straightforward (I rarely include the (default) index when saving datasets).

```
df.to_csv('marks_2.csv', index=False)
```

- CSV has become the default file format in Data Mining application especially for 'informal' datasets.
 - ✓ human readable, easy to generate / parse (if correct).
 - **X** Can be highly redundant, slow to input/output.
 - X No meta information.
- Other formats are better for speed and resulting file size and for saving meta data not supported by CSV (such as columns datatypes, category information, etc).

data science: The Best Format to Save Pandas Data

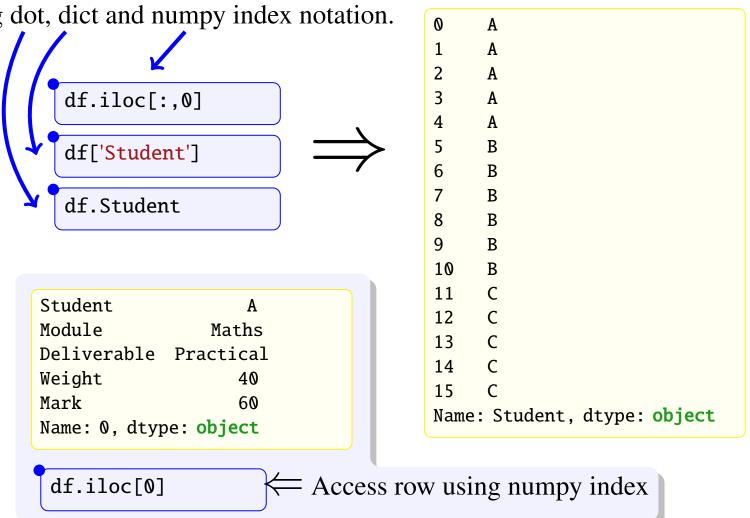

Part III

Filtering

Selecting individual rows/columns results in a series

Columns can accessed using dot, dict and numpy index notation.

df.head(1000)

Student Module Deliverable Weight Mark

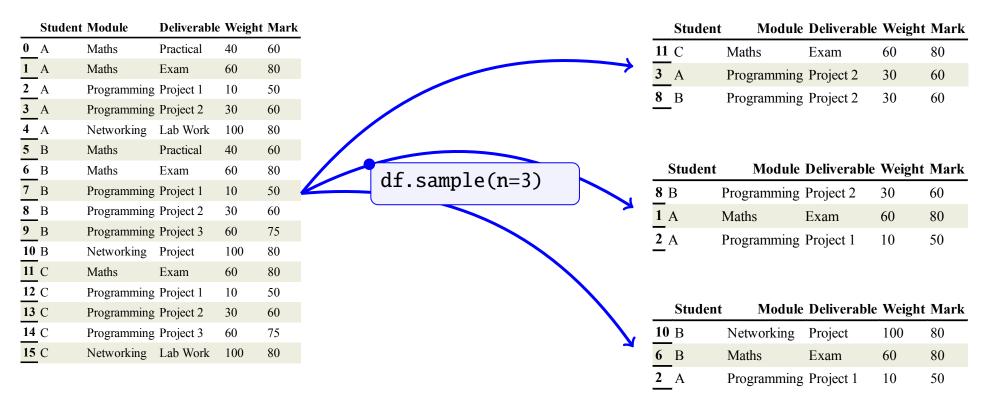

criteria = ((df.Mark<50) & (df.Module=='Maths')) | ((df.Mark<70) & (df.Module!='Maths'))
columns = ['Module', 'Student', 'Mark']

df.loc[criteria, columns]</pre>

Sampling

The sample function selects a random subset of the dataframe rows.

- Either specify the number of rows (as an integer) or fraction of the data (as a float).
- Can set the seed using random_state parameter for reproducible samples.

Part IV

Sorting

Sorting

A pandas dataframe has two sorting operations:

- sort_index() orders rows based on current index.
- sort_values(COLUMNS) orders rows based on single column or list of columns.

Two important modifications:

- By default, the sort order is in ascending. Set parameter ascending=False to reverse this.
- By default, a new dataframe is returned with desired sort order, set parameter inplace=True to update current dataframe instead (then no output is generated).

Studen	t Module	Deliverable	Weight	Mark		Student	Module	Deliverable	Weight	Mark

Part V

Defining New Columns

Defining new columns — row-wise operation

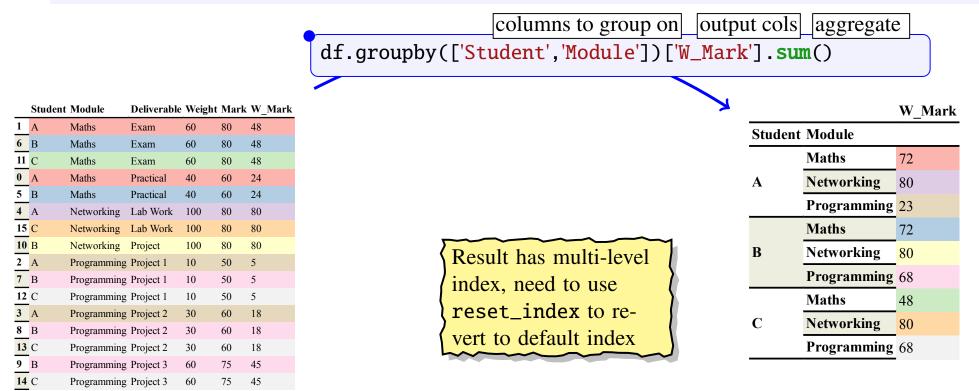

We want to compute the weighted mark for each module for each student. Two steps:

- Create column, W_Mark, to store the weighted mark for each deliverable. This is a row by row calculation only need data in current row to compute the result.
- Create column, M_Mark, to store the module mark for each student. This is a group calculation need all rows for that student and module to compute the result.

Student	Module	Deliverable	Weigh	t Mark						Student	Module	Deliverable	Weight	Mark	W_Mark
1 A	Maths	Exam	60	80						1 A	Maths	Exam	60	80	48
6 B	Maths	Exam	60	80						6 B	Maths	Exam	60	80	48
11 C	Maths	Exam	60	80						11 C	Maths	Exam	60	80	48
0 A	Maths	Practical	40	60						0 A	Maths	Practical	40	60	24
5 B	Maths	Practical	40	1.651-		1.17	16 1	1 16	1 //	100	Maths	Practical	40	60	24
4 A	Networking	Lab Work	100	df['W	_Mai	rk'] =	df.Weig	ht * df.	Mark //	100	etworking	Lab Work	100	80	80
15 C	Networking	Lab Work	100	80						13 (Networking	Lab Work	100	80	80
10 B	Networking	Project	100	80						10 B	Networking	Project	100	80	80

9 B	Programming	Project 3	60	75	Ĺ		~~		\	9 B	Programming	Project 3	60	75	45
14 C	Programming	Project 3	60	75						14 C	Programming	Project 3	60	75	45

Defining new columns — group aggregate result

- Create column, W_Mark, to store the weighted mark for each deliverable. This is a row by row calculation only need data in current row to compute the result.
- Create column, M_Mark, to store the module mark for each student. This is a group calculation need all rows for that student and module to compute the result.

Defining new columns — group aggregate result

columns to group on output cols aggregate

df.groupby(['Student','Module'])[['W_Mark']].sum().reset_index()

	Student	Module	Deliverable	Weight	Mark	W_Mark
1	A	Maths	Exam	60	80	48
6	В	Maths	Exam	60	80	48
11	С	Maths	Exam	60	80	48
0	A	Maths	Practical	40	60	24
5	В	Maths	Practical	40	60	24
4	A	Networking	Lab Work	100	80	80
15	С	Networking	Lab Work	100	80	80
10	В	Networking	Project	100	80	80
2	A	Programming	Project 1	10	50	5
7	В	Programming	Project 1	10	50	5
12	С	Programming	Project 1	10	50	5
3	A	Programming	Project 2	30	60	18
8	В	Programming	Project 2	30	60	18
13	C	Programming	Project 2	30	60	18
9	В	Programming	Project 3	60	75	45
14	С	Programming	Project 3	60	75	45

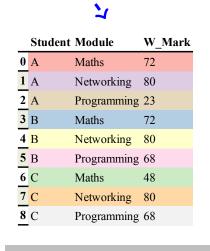

This is the required result and we can save this to a new dataframe. However, we often want to put this into to out original dataframe as an extra column. Only problem we have different rows so can't just assign to a new column — need to use transform function.

	Student	Module	$\mathbf{W}_{\underline{}}$	_Mark
0	A	Maths	72	
1	A	Networking	80	
2	A	Programming	23	
3	В	Maths	72	
4	В	Networking	80	
5	В	Programming	68	
	C	Maths	48	
7	C	Networking	80	
8	C	Programming	68	

```
columns to group on output cols aggregate

df['M_Mark'] = df.groupby(['Student','Module'])[['W_Mark']].transform(sum)
```

	Student	Module	Deliverable	Weight	Mark	W_	_Mark
1	A	Maths	Exam	60	80	48	
6	В	Maths	Exam	60	80	48	
11	C	Maths	Exam	60	80	48

The transform broadcasts the result for each group over every row in that group.

Part VI

Review Exercises

Review Exercises

Generate the following reports:

- Number of deliverables by each student.
- 2 List and rank deliverables by grade.
- Top 2 deliverables (by grade).
- Top 2 module (by average grade).
- Top 2 modules (by minimum grade).
- Modules (by minimum grade).

Harder exercises (new functions)

• List which students missed which deliverables.

(value_counts, or groupby and count)

(sort_values, rank)

(pivot, melt)
